Modaris V6r1 Full Version results Lectra modaris expert v7r2 3d fullA .Associations between serological markers and the presence of pathogenic bacteria in diarrheic calves. The occurrence of diarrhea is a major problem in farm animals such as calves. Often, associated with the disease there are the presence of pathogenic bacteria that can affect negatively the animal and the milk yield. The objective of this study was to evaluate the association between the serological markers of infection and the presence of pathogenic bacteria in the milk. For this, two different groups were established, one composed by 10 healthy calves and the other composed by 30 calves with diarrhea. Samples of milk and blood serum were collected from both groups during six times (4 days before and 10 days after the onset of diarrhea) and tested for antigen-specific antibodies using an indirect ELISA. The calves with diarrhea had higher levels of antibody response in all studied times (in general, higher than in the healthy animals) to Bacteroides gasseri and Clostridium perfringens antigens. The presence of the protein band of molecular weights between 28 and 45 kDa in the SDS-PAGE indicates the presence of antibodies against these antigens. The association between the serological markers and the presence of pathogenic bacteria can be used as an indicator of the healthy and sick status of the animals that would allow a better approach in the control of diarrhea in calves.Endothelial derived procoagulant microparticles in sepsis: modulation by L-arginine. Sepsis may be associated with disseminated intravascular coagulation (DIC). High levels of endothelial derived procoagulant microparticles (EMP) are present in sepsis. EMP depend on arginase activity and
